

Field Development Plans: The Digital Blueprint

A comprehensive master strategy for transforming discovered hydrocarbons into producing assets—from initial exploration to final abandonment.

THE FIELD DEVELOPMENT PLAN

A dynamic blueprint integrating technical, economic, and environmental considerations to extract hydrocarbons efficiently, safely, and profitably. It guides investment decisions, regulatory approvals, and operational execution.

1. DEFINE WELL STRATEGY

Determining the optimal number, trajectory, and location of wells to maximize field value.

2. RECOVERY OPTIMISATION

Engineering subsurface strategies to maximize long-term hydrocarbon extraction.

3. PLAN INFRASTRUCTURE

Designing surface facilities and transport architecture to process and deliver the product.

The FDP Lifecycle

1. Initial Planning & Feasibility

2. Design & Engineering

3. Drilling & Well Completion

4. Production Facilities

5. Field Optimisation

6. Decommissioning

Continuous Economic & Risk Assessment

Design and Engineering Matrix

Subsurface Execution: Interaction with the Reservoir

Drilling Operations

Design of well trajectory and complex casing programmes.

Directional and horizontal drilling for enhanced reservoir contact.

Managed pressure drilling deployed in challenging formations.

Well Completion

Casing and cementing strategies for absolute zone isolation.

Precision perforation and targeted stimulation techniques.

Installation of specialized artificial lift systems.

Surface Infrastructure: Conversion & Export

Converting raw hydrocarbons into export-ready products.

Zone 1: Separation Units

Multiphase systems designed to precisely separate oil, gas, and water.

Zone 2: Compression Systems

Advanced compressor networks to prepare gas for long-distance transport and export.

Zone 4: Environmental Control

Dedicated systems to manage flaring, treat produced water, and strictly limit emissions.

Zone 3: Storage & Export

Robust networks of tanks, pipelines, and marine terminals for final product delivery.

The Dynamic Phase: Field Optimisation

Stage 4: Enhanced Recovery
Implementing advanced techniques like CO₂ injection and polymer flooding to sweep remaining reserves.

Stage 3: Pressure Maintenance
Executing waterflooding or gas injection strategies to sustain natural drive.

Stage 1: Reservoir Monitoring
Production logging, comprehensive well testing, and real-time pressure monitoring.

Stage 2: Production Optimisation
Surface choke adjustments, strategic recompletions, and deployment of digital oilfield technologies.

The Financial Engine: Cost & Profitability

Sensitivity and uncertainty analyses are constantly run to account for fluctuating oil prices, technical risks, and regulatory shifts.

Decommissioning: Leaving No Trace

Safe and environmentally responsible closure ensuing regulatory compliance and environmental protection at the end of field life.

1

Step 1: Well Plugging

Installation of permanent, engineered barriers to permanently isolate hydrocarbon-bearing zones.

2

Step 2: Facility Decommissioning

The systematic dismantling and removal of platforms, pipelines, and surface processing units.

3

Step 3: Site Restoration

Complete ecological rehabilitation to meet stringent environmental standards and return the site to its natural state.

The Regulatory and Standards Bedrock

The Unified Strategy

An effective Field Development Plan is a dynamic roadmap transforming discovered accumulations into producing assets. Success relies on continuous optimization across five integrated pillars.
